Introduction

Two-dimensional digital model for analysis of direct current corona field and induced electrohydrodynamic air flow field in wire-to-plane electrode system is presented. The model based on the finite-difference method in polar coordinate system for corona field computation is suitable to use in usual personal computers. Results of computation of current-voltage discharge characteristic are compared to use in usual personal computers. Results of computation of current-voltage discharge characteristic are compared with experimental one. The digital model of electrohydrodynamic air flow field consists of finite-difference approximation of the Navier-Stokes equation and the continuity equation in Cartesian coordinates. The partial derivatives of the charge conservation equation

\[ \frac{\partial \rho}{\partial r} + r \frac{\partial V}{\partial \varphi} = \frac{\rho^2}{\varepsilon} \]  

are of the form:

\[ \frac{\partial V}{\partial r} = \frac{V_S a_Q}{a_s (a_Q + a_S)} + \frac{V_Q a_S}{a_Q (a_Q + a_S)} + \frac{V_O (a_Q - a_S)}{a_Q a_S}, \]  

\[ \frac{r \partial V}{\partial \varphi} = \frac{V_P a_R}{a_P (a_P + a_R)} + \frac{V_R a_P}{a_R (a_P + a_R)} + \frac{V_O (a_P - a_R)}{a_P a_R}, \]  

where potential is represented by \( V \) and space charge density correspondingly by \( \rho \). Distances from the central node of polar grid \( O \) to the neighbor nodes \( P, Q, R \) and \( S \) are denoted by \( a_P, a_Q, a_R \) and \( a_S \). Boundary conditions for potential are Dirichlet and Neumann type. Boundary condition for space charge density on the surface of the wire is determined iteratively until Kaptzov's condition is established [7]. The number of nodes in polar grid is 518.
for the values of geometrical dimensions of the electrode system (Fig. 1) \( r_0 = 0.05 \text{ mm} \) and \( h = 12.0 \text{ mm} \).

**Fig. 1.** Coulomb force components

Components of the Coulomb force per unit volume are determined as the product of space charge density and the field strength:

\[
F_r = \rho E_r = -\frac{\partial V}{\partial r}, \quad (7)
\]

\[
F_\phi = \rho E_\phi = -\frac{\partial V}{\partial \phi}. \quad (8)
\]

Correctness of the model is checked by comparison of the numerical solution of Laplace's equation with analytical solution of an electrostatic field in wire-to-plane electrode system. Average difference between numerical and analytical values of electrostatic field potential on the axis of symmetry \( (x = 0) \) is 0.2 % for the number of nodes of polar grid \( n = 518 \). Additional test of the numerical corona field model is comparison of numerical data of the current-voltage characteristic with the experimental one. Maximum difference between numerical and experimental values of linear current density corresponding to the voltage value \( U = 7.0 \text{ kV} \) is 150 \( \mu\text{A/m} \). Spatial components of Coulomb force calculated in rectangular coordinate system is shown in Fig. 2.

**Fig. 2.** Spatial force vectors, recounted by rectangular grid force projections in elements of rectangular grid

**Fig. 3.** Computational grid with square elements

It is clear from Fig. 4 and Fig. 5 that Coulomb force strength has an influence to air velocity, but almost no influence to vectors direction, because the ratio of spatial

**Numerical model of electro hydrodynamic air flow field**

Electrohydrodynamic air flow is determined by the system of equations comprising of the Navier-Stokes and flow continuity equations. Emitting electrode with the ionization zone cross section area is negligible in comparison with an overall area of the field therefore the wire electrode can be represented as a point. Cartesian system of coordinates can be used to reduce the number of nodes. Finite-difference approximation of the Navier-Stokes and the flow continuity equations for this system of coordinates contains the Coulomb force components \( F_x, F_y \) and the flow velocity components \( w_x, w_y \) [7]:

\[
w_x^{(r+1)} = \frac{F_x}{\rho_v} + \frac{1}{a^2} \left( \frac{w_{xP} - w_{xR}}{a} + \frac{w_{xQ} + w_{xS}}{a} + \frac{4w_{xC}}{a^2} \right) - w_x \Delta \tau + \omega_x^{(r)}, \quad (9)
\]

\[
w_y^{(r+1)} = \frac{F_y}{\rho_v} + \frac{1}{a^2} \left( \frac{w_{yP} - w_{yR}}{a} + \frac{w_{yQ} + w_{yS}}{a} + \frac{4w_{yC}}{a^2} \right) - w_y \Delta \tau + \omega_y^{(r)}, \quad (10)
\]

where \( w_x^{(r+1)} \) is the velocity \( x \) component value of new iteration, \( w_x^{(r)} \) is the value of previous iteration, \( w_{xP}, w_{xR}, w_{xS}, w_{xQ} \) are the \( x \) components of velocities in the neighbour nodes, \( w_{xO} \) is the \( x \) axis component of average velocity in the square (Fig. 3), \( \Delta \tau \) - variation of time between iterations, \( a \) – distance between nodes, regular in all the grid \( (a = 2 \text{ mm} \) for Fig. 4).
force components vary insignificantly, only changes their module.

Fig. 4. Electrohydrodynamic air flow distribution in the electrode system for \( h = 12 \) mm

Dependence of the air flow velocity in the points of the line \( x = 2 \) mm = const upon the distance from the plane electrode is given in Fig. 6. Maximum value of air flow velocity above the wire is approximately 4 m/s.

Fig. 6. Air flow velocity at first column away from the axis of symmetry for various wire voltages

Fig. 7. Air flow velocity on the first line above the plane for various wire voltages

The growth of the volume flow-rate with the variation of coordinate \( y \) in the plane \( x = 24 \) mm = const is presented in Fig. 8. An overall volume flow-rate through this plane is \( 6 \times 10^{-3} \) m\(^3\)/s.

Fig. 8. Growth of the volume flow-rate with variation of \( y \) coordinate in the plane \( x = 24 \) mm = const

The similar graphic for the plane \( y = 24 \) mm = const is given in Fig.9. Data given in Fig. 4, Fig. 8 and Fig 9 correspond to the discharge voltage \( U = 10 \) kV.

Fig. 9. Growth of the volume flow-rate with variation of \( x \) coordinate in the plane \( y = 24 \) mm = const

Hot-wire anemometer DO 9847K is used for experimental test of computed data. The diameter of the anemometer probe is 8 mm whereas the spacing between electrodes is 12 mm. Therefore it is no possibility to measure an air flow velocity in the volume between electrodes for the risk of spark discharge and essential distortion not only the corona field, but also the air flow field. Measured value of the airflow velocity in the point \( x = 60 \) mm at the surface of plane electrode is 1.02 m/s, and the numerical value is 1.57 m/s, the difference between the
results is 35%. Coincidence of computed and measured results is only qualitative. This is in agreement with the results of other researchers [3].

Maximum value of the total volume flow-rate is near the $6 \times 10^{-3}$ m$^3$/s at the mentioned conditions.

Measured and computed values of air flow velocities coincide qualitatively because of the difference between measured and computed values totals about 30%.
