Abstract—The paper presents the human Affect Reward Based Automation Ambient Comfort Controller (ACARBC) as the interconnected cloud computing intelligent services that provide intelligent calculus for any instrumented interconnected environment sense and control system. The ACARBC has been modelled and, as the experimental results show, that an environmental state characteristics that create an optimum ambient comfort can be obtained by ACAR index. The ACAR index is dependent on human physiological parameters: the temperature, the ECG- electrocardiogram and the EDA-electro-dermal activity. The fuzzy logic is used to approximate the ACAR index function by defining two fuzzy inference systems: the Arousal-Valence System, and the Ambient Comfort Affect Reward (ACAR) System. The Radial Basis Neural Network is used as the main component of the ACARBC to performing of two roles - the policy structure, known as the Actor, used to select actions, and the estimated value function, known as the Critic that criticizes the actions made by the Actor. The Critic in this paper was used as a value function approximation of the continuous learning tasks of the ACARBC.

Index Terms—Ambient intelligence, automatic control, emotion recognition, human computer interaction, machine learning.

I. INTRODUCTION

The IBM vision of the smarter home enabled by cloud technology shows that such “smarter home” becomes “instrumented, interconnected and intelligent”. “Today’s Internet of people is evolving into an “Internet of things”, and by 2013, 1.2 billion connected consumer electronics devices are expected in the more than 800 million homes with broadband connections”. Compared with previous attempts to enable the “smart home,” where the intelligence was based on centralized control through a home server or gateway, the intelligence and with it the complexity in the new smarter home is moved out from the home onto the network, or more precisely the Internet cloud. By IBM, “*Instrumented* is the ability to sense and monitor changing conditions”. Instrumented devices provide increasingly detailed information and control about their own functioning and also provide information about the environment in

which they operate. “*Interconnected* is the ability to communicate and interact, with people, systems and other objects”. Interconnected devices make possible remote access to information about a device and control of the device. This enables services throughout the Internet, removing complexity from the home and lowering costs for the service providers. At the same time, it supports the aggregation of information and control of devices throughout the network. This means that consumers can get a consistent view of their devices, both from home and from mobile devices. For service providers, it provides an aggregate view of customer characteristics according to criteria such as geographic location, consumption patterns, or types of service. “*Intelligent* is the ability to make decisions based on data, leading to better outcomes”. Intelligent devices support the optimization of their use, both for the individual consumer and for the service provider. For instance, “a utility can send signals to consumers’ homes to manage discretionary energy use in order to reduce peak loads. By coordinating this process throughout an entire service area, the utility can optimize the peak reduction, while saving the consumers money on their bill”.

Inspired by investigations of thermal comfort, indoor air quality and adequate illuminance by using the Predicted Mean Vote Index (PMV) [1]–[3], the human Ambient Comfort Affect Reward, the ACAR index is proposed for automatic quality control of heating/ventilation and lighting automation devices [4], [5]. This controller is planned to be used to improve energy savings in the sustainable environment. Specifically, it predicts the indoor lighting, heating and air quality conditions at a given time by measuring integrated ACAR index that defines ambient comfort affect to the human. Principles of development of the intelligent cloud services of Ambient Comfort Affect Reward Based heating, ventilation, and air conditioning Controller, the ACARBC are described in this paper.

II. MODEL OF THE AMBIENT COMFORT AFFECT REWARD BASED HEATING, VENTILATION, AND AIR CONDITIONING CONTROLLER

The developing process of the smart environment is based on automatic control which adopts environment by smart sensing of human physiological signals. The architecture of

The RBF network is a linear function approximation using RBFs for its features. The *Learning Algorithm* is used to adopt RBF network weights in order to fit *Actor* and *Critic* functions. The feature of the *Actor-Critic* learning is that the *Actor* learns the policy function and the *Critic* learns the value function using the Temporal Difference (TD) method simultaneously [5]. The TD error $\delta_{TD}(t)$ is calculated by the temporal difference of the value function between successive states in the state transition as

$$\delta_{TD}(t) = r(t) + \gamma V(t+1) - V(t), \quad (4)$$

where $r(t)$ is the external reinforcement reward signal, $0 < \gamma < 1$ denotes the discount factor that is used to determine the proportion of the delay to the future rewards. The TD error indicates, in fact, the goodness of the actual action. Therefore, the weight vector θ of the policy function and the value function are updated as

$$\vec{\theta}_{t+1} = \vec{\theta}_t + \alpha \delta_t \vec{e}_t, \quad (5)$$

where α is the learning rate and the eligibility trace, e can be calculated by:

$$\begin{cases} e_0 = 0, \\ e_{t+1} = \gamma \lambda e_t + \nabla_{\theta_t} V(t). \end{cases} \quad (6)$$

III. MODELLING CLOUD SERVICES FOR AMBIENT COMFORT AFFECT REWARD BASED CONTROLLER

The prediction of action by ambient environmental state and physiological parameters of the human is based on reinforcement learning and the model of ACARBC implemented as a cloud services is shown in Fig. 2.

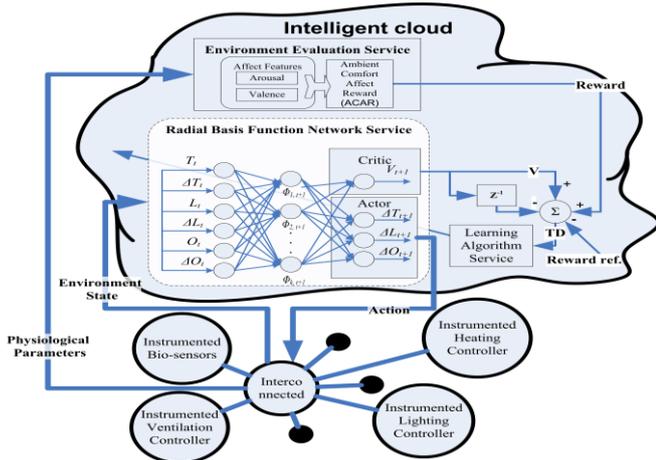

Fig. 2. Intelligent subsystem implementation as a cloud services for ambient comfort control.

The implementation of main intelligent calculus of ACARBC as a cloud services reduces IT management cost, the complexity of performing tasks, increases efficiency of use provisioned resources, service accessibility flexibility, simplifies instrumented interconnected devices of entire ACAR system. The ACARBC consists of the following parts: the *Environment Evaluation Service*, the *Radial Basis*

Neural Network Service, and the *Learning Algorithm Service*. Each service is implemented as described previously using fuzzy inference systems, RBF neural networks and learning algorithms. Using interface, the ACARBC services can be accessible for any instrumented interconnected environment sense and control system.

IV. EMPIRICAL RESULTS OF SIMULATION ACARBC

The main characteristic of ACARBC is the TD error $\delta_{TD}(t)$ dynamics. The optimum state is obtained if this parameter converged to 0 i.e. no need any change of the state. Using MatLab software tools we applied the proposed ambient comfort control algorithm to track the optimal environmental state. The pseudo code is shown in Fig. 3. The corresponding parameters (γ - discount factor, λ - decay factor, α - the learning rate) for the ACARBC are set for different experimental setups. The detailed simulation results are shown in Fig. 4. The Simulation results indicate that the proposed ACARBC can be stable ($\delta_{TD}(t) - \text{converges to } 0$) using appropriate parameters (Fig. 4 (a, b)). As well as the $\delta_{TD}(t)$ -can diverge (Fig. 4(c)). As we can see in Fig. 4(d) starting from the initial state: temperature - 13, lighting - 55 and air conditioning - 65 the optimum state is obtained.

```

Input: statet=0 // the initial state
Output: state trace
          action trace
          temporal difference trace
          value trace
Initialize:  $\Delta reward$  // the change of the reward
              ARVAt=0 // the initial arousal-valence value vector
              ACARt=0 // the Ambient Comfort Affect Reward center
              // the centers of basis functions
               $\sigma$  // the width of basis functions
               $\gamma$  // the discount factor
               $\lambda$  // the decay factor

The TD error $\delta_{TD}(t)$ dynamics using corresponding controller parameters: a – $\gamma=0.8$, $\lambda=0.5$, $\alpha=0.2$; b – $\gamma=0.8$, $\lambda=0.5$, $\alpha=0.01$; c – $\gamma=0.9$, $\lambda=0.9$, $\alpha=0.02$; d – The dynamics of ambient environment state using corresponding controller parameters: $\gamma=0.8$, $\lambda=0.5$, $\alpha=0.2$.

V. CONCLUSIONS

In this paper, the human Affect Reward Based Automation Ambient Comfort Controller (ACARBC) is proposed as the interconnected cloud computing intelligent services that provide intelligent calculus for any instrumented interconnected environment sense and control system.

The ACARBC has been modelled and, as the experimental results show, that an environmental state characteristics that create an optimum ambient comfort can be obtained by ACAR index. The ACAR index is dependent on human physiological parameters: the temperature, the *ECG*- electrocardiogram and the *EDA*-electro-dermal activity.

For future works, it is necessary to investigate the stability of ACARBC as it has been shown that it varies for different controller parameters.
